

# Bayesian Model Updating: Going On-line with Engineering Problems

Speaker: Adolphus Lye

Institute for Risk and Uncertainty

12-February-2021

# Introduction: Who Am I?

- 3<sup>rd</sup>-Year PhD Student;
- Supervisors:
  - a Professor E. Patelli [University of Strathclyde]
  - b Professor A. Ciciello [T. U. Delft]
- Project: On-line Bayesian Model Updating for Real-time Damage Assessment in Dynamical Structures;
- Funding: Singapore Nuclear Research and Safety Initiatives (SNRSI);
- Research Interests:
  - i Probabilistic Safety Assessment for Light Water Reactors;
  - ii Bayesian Model Updating for Structural Health Monitoring;
  - iii Model Uncertainty in Bayesian Inference Problems
  - iv Sampling Techniques for Bayesian Inference

# Introduction: Presentation Outline

## Today's Special

- ➊ Overview of Bayesian Model Updating;
- ➋ Tools for Bayesian Model Updating + Simple Application Problems;
- ➌ Introduction of On-line Bayesian Model Updating;
- ➍ Tool for On-line Bayesian Model Updating + Application Problem;
- ➎ Overall Evaluation of Techniques;
- ➏ Concluding Remarks

# 1. Overview of Bayesian Model Updating

# Overview of Bayesian Model Updating

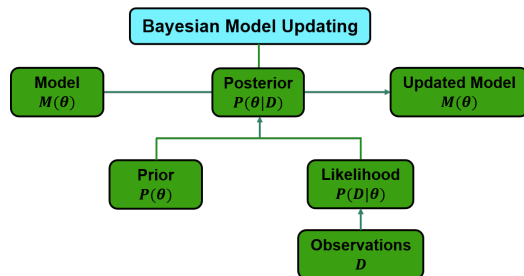

- A Probabilistic Model Updating technique based on Bayes' Inference:

$$P(\theta|\mathbf{D}) = \frac{P(\theta) \cdot P(\mathbf{D}|\theta)}{P(\mathbf{D})} \quad (1)$$

whereby:

Variable:	Description:
$\theta$	Vector of Epistemic parameter(s)
$\mathbf{D}$	Vector of Data / Observations
$P(\theta)$	Prior distribution
$P(\mathbf{D} \theta)$	Likelihood function
$P(\mathbf{D})$	Evidence / Normalization constant
$P(\theta \mathbf{D})$	Posterior distribution

- Yields a distribution of  $\theta$  rather than just a point estimate.

# Overview of Bayesian Model Updating

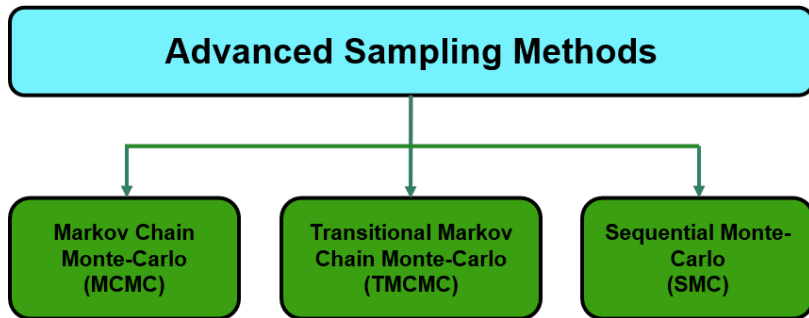

- The Evidence  $P(\mathbf{D})$  is a constant and independent of  $\theta$ ;
- The Posterior  $P(\theta|\mathbf{D})$  can therefore be expressed in its un-normalized form as:

$$P(\theta|\mathbf{D}) \propto P(\theta) \cdot P(\mathbf{D}|\theta) \quad (2)$$

- Thus, the main ingredients required are:  $P(\theta)$  and  $P(\mathbf{D}|\theta)$ ;
- But due to  $P(\mathbf{D}|\theta)$  being un-normalized, standard Monte-Carlo approach becomes inapplicable;
- Sophisticated tools are needed in this case.

# Overview of Bayesian Model Updating

## 2. Tools for Bayesian Model Updating

[Markov Chain Monte-Carlo (MCMC)]

# Markov Chain Monte-Carlo (MCMC)

- Conceptualised by Nicholas Metropolis;  
(1915 – 1999)
- Adopts the use of Markov Chains to generate samples;
- New samples are generated based on current sample via a Proposal distribution  $q(\boldsymbol{\theta}^*|\boldsymbol{\theta}) \sim N(\boldsymbol{\theta}, \sigma_p)$ ;
- The chain will run until it approaches “Stationary distribution”;
- This “Stationary distribution” is assumed to correspond to  $P(\boldsymbol{\theta}|\boldsymbol{D})$ ;
- Accept-Reject algorithm: Metropolis-Hastings.

# Markov Chain Monte-Carlo (MCMC)

Note: Should  $\theta^*$  be accepted, the Proposal distribution will shift from its current location (in red), to the new one represented by the blue dotted curve. Otherwise, the Proposal distribution remains in its current location.

# Application Problem A

# Application Problem A: 1DOF Spring-Mass System

- Consider a 1DOF Spring-Mass system whose spring stiffness  $k$  obeys Hooke's Law:

$$F = -k \cdot d$$

where  $F$  is the measured restoring force,  $d$  is the displacement length of the spring from its rest length;

- True value of  $k = 263.0 \text{ N/m}$ ;
- 10 sets of synthetic measurements of  $F$  are obtained from 10 values of  $d$  are generated according to:

$$\tilde{F}_n = F_n + \epsilon_n$$

where  $n = 1, \dots, 10$ ;  $\epsilon_n \sim N(0, \sigma_n)$  for which  $\sigma_n = 1.0 \text{ N}$ ;

- Least-square estimate of  $k = 245.73 \text{ N/m}$ .

# Application Problem A: 1DOF Spring-Mass System

- Consider a 1DOF Spring-Mass system whose spring stiffness  $k$  obeys Hooke's Law:

$$F = -k \cdot d$$

where  $F$  is the measured restoring force,  $d$  is the displacement length of the spring from its rest length;

- True value of  $k = 263.0 \text{ N/m}$ ;
- 10 sets of synthetic measurements of  $F$  are obtained from 10 values of  $d$  are generated according to:

$$\tilde{F}_n = F_n + \epsilon_n$$

where  $n = 1, \dots, 10$ ;  $\epsilon_n \sim N(0, \sigma_n)$  for which  $\sigma_n = 1.0 \text{ N}$ ;

- Least-square estimate of  $k = 245.73 \text{ N/m}$ .

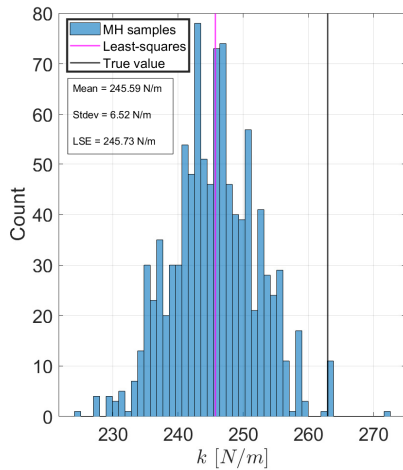

# Application Problem A: 1DOF Spring-Mass System

- The Bayesian model updating set-up to infer  $\theta = k$  follows:
  - ❶  $P(k)$  is set as a Uniform prior with range:  $k_1 \in [1.0, 1.0 \times 10^3] \text{ N/m}$ ;
  - ❷  $P(\mathbf{D}|\theta)$  is set as a Normal distribution:

$$P(\mathbf{D}|\theta) = \prod_{n=1}^{10} \frac{1}{\sigma_n \cdot \sqrt{2\pi}} \cdot \exp \left[ -\frac{(\tilde{F}_n - F_n(\theta))^2}{2\sigma_n^2} \right]$$

- $\sigma_p = 30.0 \text{ N/m}$  to ensure acceptance rates of the MCMC sampler is as close to 0.234;
- $N_{samples} = 1000$  obtained from posterior via MCMC (i.e. MH).

# Application Problem A: 1DOF Spring-Mass System

Note: MH took 0.31 s with acceptance-rate 0.254.

## 2. Tools for Bayesian Model Updating

[Transitional Markov Chain Monte-Carlo (TMCMC)]

# Transitional Markov Chain Monte-Carlo (TMCMC)

- Based on Adaptive Metropolis-Hastings (AMH) algorithm;
- Adopts the use “transitional” distributions,  $P^j$ :

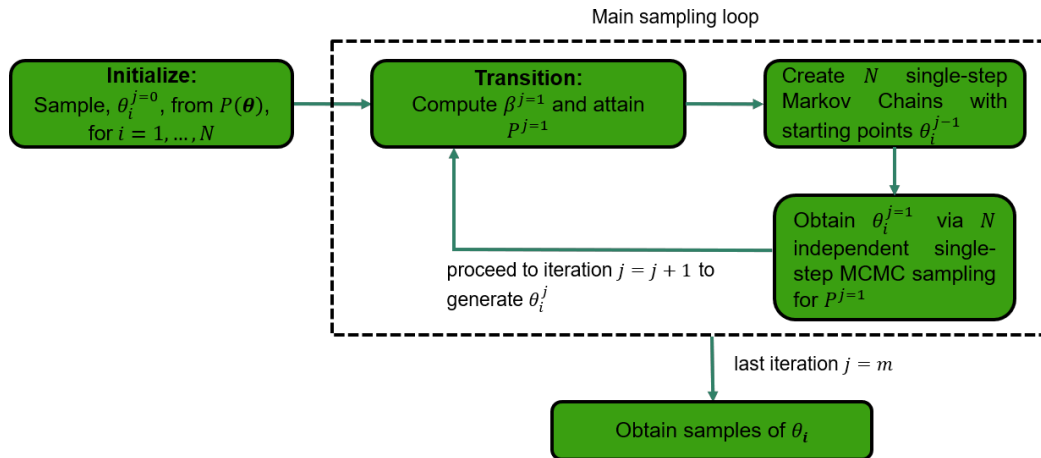

$$P^j = P(\mathbf{D}|\boldsymbol{\theta})^{\beta_j} \cdot P(\boldsymbol{\theta})$$

where  $j = 1, \dots, m$  denotes the iteration number, and  $\beta_j$  is such that  $\beta_0 = 0 < \beta_1 < \dots < \beta_{m-1} < \beta_m = 1$

- Change in  $\beta_j$  has to be small to ensure smooth, gradual transition;
- Performs parallel sampling:  $N$  samples obtained per iteration;
- Generates the solution for  $P(\mathbf{D})$  as by-product.

# Transitional Markov Chain Monte-Carlo (TMCMC)

# Application Problem B

# Application Problem B: 2DOF Shear Building

- Consider a 2DOF 2-storey Shear building structure whose dynamics is described by:

$$\mathbb{M}\ddot{\mathbf{x}} + \mathbb{K}\mathbf{x} = F(t)$$

where  $F(t)$  is the external force function,  $\mathbb{M}$  is the Mass matrix, and  $\mathbb{K}$  is the Stiffness matrix defined respectively as:

$$\mathbb{M} = \begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix}$$

$$\mathbb{K} = \begin{bmatrix} k_1 + k_2 & -k_2 \\ -k_2 & k_2 \end{bmatrix}$$

- Solving the second-order differential equation for  $F(t) = 0$  yields 2 distinct eigenfrequencies.

# Application Problem B: 2DOF Shear Building

- The set-up can be re-represented as a coupled oscillator as seen on the left;
- The true values of the defined parameters are:

Parameter:	Value:
$m_1$	$1.0 \times 10^4 \text{ kg}$
$m_2$	$1.0 \times 10^4 \text{ kg}$
$k_1$	$5.0 \times 10^3 \text{ N/m}$
$k_2$	$1.5 \times 10^4 \text{ N/m}$

- 10 sets of synthetic measurements of  $f_1$  and  $f_2$  are generated according to:

$$\tilde{f}_l = f_l + \epsilon_l$$

where  $l = 1, 2$ ;  $\epsilon_l \sim N(0, \sigma_l)$  for which  $\{\sigma_1, \sigma_2\} = \{1.0, 0.1\} \text{ Hz}$ ;

- True values of eigenfrequencies:  $\{f_1, f_2\} = \{3.271, 0.229\} \text{ Hz}$ .

# Application Problem B: 2DOF Shear Building

- The set-up can be re-represented as a coupled oscillator as seen on the left;
- The true values of the defined parameters are:

Parameter:	Value:
$m_1$	$1.0 \times 10^4 \text{ kg}$
$m_2$	$1.0 \times 10^4 \text{ kg}$
$k_1$	$5.0 \times 10^3 \text{ N/m}$
$k_2$	$1.5 \times 10^4 \text{ N/m}$

- 10 sets of synthetic measurements of  $f_1$  and  $f_2$  are generated according to:

$$\tilde{f}_l = f_l + \epsilon_l$$

where  $l = 1, 2$ ;  $\epsilon_l \sim N(0, \sigma_l)$  for which  $\{\sigma_1, \sigma_2\} = \{1.0, 0.1\} \text{ Hz}$ ;

- True values of eigenfrequencies:  $\{f_1, f_2\} = \{3.271, 0.229\} \text{ Hz}$ .

# Application Problem B: 2DOF Shear Building

- The Bayesian model updating set-up to infer  $\boldsymbol{\theta} = \{k_1, k_2\}$  follows:
  - ❶  $P(k_1)$  is set as a Uniform prior with range:  $k_1 \in [1.0, 1.0 \times 10^5] \text{ N/m}$ ;
  - ❷  $P(k_2)$  is set as a Uniform prior with range:  $k_2 \in [1.0, 1.0 \times 10^5] \text{ N/m}$ ;
  - ❸  $P(\mathbf{D}|\boldsymbol{\theta})$  is set as a Bi-Normal distribution:

$$P(\mathbf{D}|\boldsymbol{\theta}) = \prod_{n=1}^{10} \frac{1}{\sigma_1 \cdot \sigma_2 \cdot 2\pi} \cdot \exp \left[ -\frac{(\tilde{f}_{1,n} - f_1(\boldsymbol{\theta}))^2}{2\sigma_1^2} - \frac{(\tilde{f}_{2,n} - f_2(\boldsymbol{\theta}))^2}{2\sigma_2^2} \right]$$

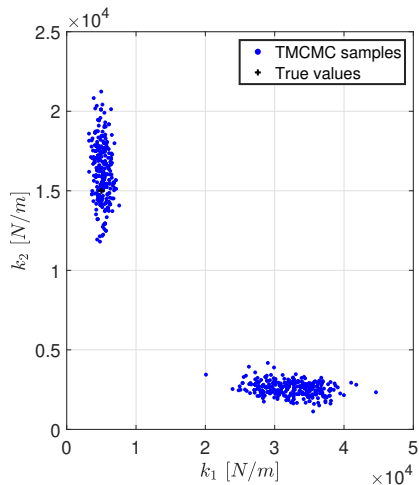

- $N_{samples} = 1000$  obtained from posterior via TMCMC;
- Results will be compared against MCMC (i.e. MH) with  $\Sigma_p = 6.0 \times 10^6 \cdot I$  to achieve acceptance rates as close to 0.234.

# Application Problem B: 2DOF Shear Building

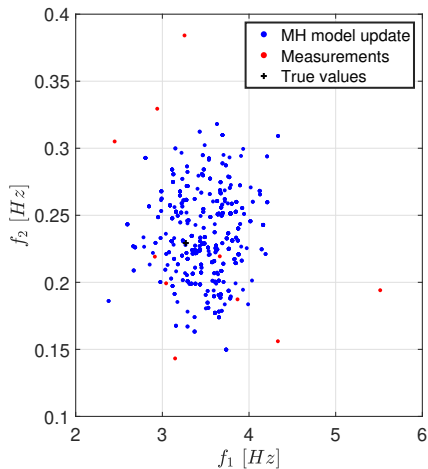

# Application Problem B: 2DOF Shear Building

Note: TCMC took 22.00 s while MH took 0.27 s (with acceptance rate 0.239).

# Application Problem B: 2DOF Shear Building

# Some Remarks

- So far, we only consider the case where a complete data-set is made “available”;
- As such, samples are generated from static  $P(\theta|\mathbf{D})$ ;
- In reality, such assumptions are never true at all times as data can be obtained On-line;
- This is especially true for real-time monitoring of infrastructures such as Bridges, Building structures, and Dynamical systems;
- Such problems would give-rise to dynamical  $P(\theta|\mathbf{D})$ ;
- This can be addressed using On-line Bayesian Model Updating.

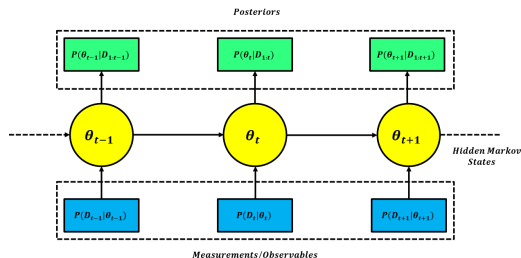

# On-line Bayesian Model Updating

- Consider a stream of data:  
 $\mathbf{D}_{1:t} = \{\mathbf{D}_1, \dots, \mathbf{D}_t\};$
- A recursive approach is adopted to update  $P(\boldsymbol{\theta}|\mathbf{D}_{1:t})$  where:

$$P(\boldsymbol{\theta}|\mathbf{D}_{1:t}) \propto P(\boldsymbol{\theta}) \cdot \prod_{j=1}^t P(\mathbf{D}_j|\boldsymbol{\theta}) \quad (3)$$

assuming independence between data-set  $\mathbf{D}_t$  obtained at time-step  $t$ , and  $\boldsymbol{\theta}$  is static;

- At each  $t$ , the previous posterior  $P(\boldsymbol{\theta}|\mathbf{D}_{1:t-1})$  is set as the new Prior to be updated with  $P(\mathbf{D}_t|\boldsymbol{\theta})$ ;
- Sampling is done sequentially: Sequential Monte Carlo (SMC) sampler

# 4. Tool for On-line Bayesian Model Updating

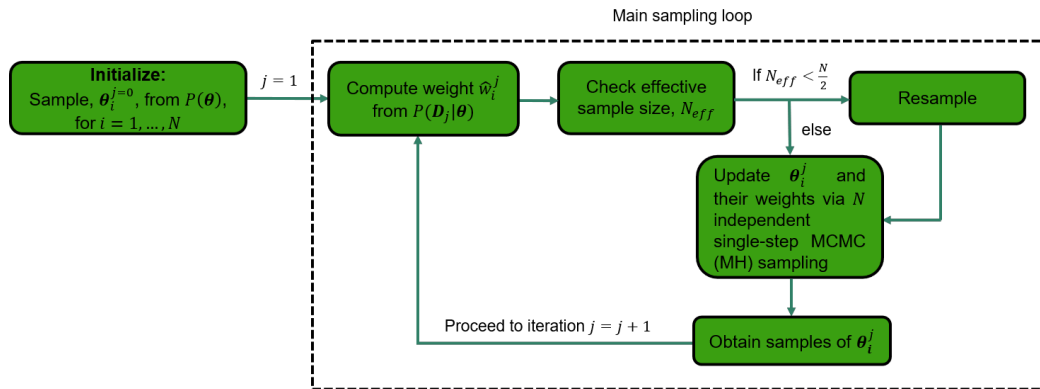

[Sequential Monte-Carlo (SMC)]

# Sequential Monte-Carlo (SMC)

- Based on the Sequential Importance Resampling (SIR) Particle-Filter algorithm;
- Designed to sample from dynamic posteriors in a sequential manner;
- Recursive algorithm;
- Utilises weights to approximate the distribution of  $\theta$ ;
- Generates the solution for  $P(\mathbf{D}_{1:t})$  at each iteration.

# Sequential Monte-Carlo (SMC)

# Application Problem B

# Application Problem B: 2DOF Shear Building

- Consider a 2DOF 2-storey Shear building structure whose dynamics is described by:

$$\mathbb{M}\ddot{\mathbf{x}} + \mathbb{K}\mathbf{x} = F(t)$$

where  $F(t)$  is the external force function,  $\mathbb{M}$  is the Mass matrix, and  $\mathbb{K}$  is the Stiffness matrix defined respectively as:

$$\mathbb{M} = \begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix}$$

$$\mathbb{K} = \begin{bmatrix} k_1 + k_2 & -k_2 \\ -k_2 & k_2 \end{bmatrix}$$

- Solving the second-order differential equation for  $F(t) = 0$  yields 2 distinct eigenfrequencies.

# Application Problem B: 2DOF Shear Building

- The true values of the defined parameters are:

Parameter:	Value:
$m_1$	$1.0 \times 10^4 \text{ kg}$
$m_2$	$1.0 \times 10^4 \text{ kg}$
$k_1$	$5.0 \times 10^3 \text{ N/m}$
$k_2$	$1.5 \times 10^4 \text{ N/m}$

- 10 sets of synthetic measurements of  $f_1$  and  $f_2$  are generated according to:

$$\tilde{f}_l = f_l + \epsilon_l$$

where  $l = 1, 2$ ;  $\epsilon_l \sim N(0, \sigma_l)$  for which  $\{\sigma_1, \sigma_2\} = \{1.0, 0.1\} \text{ Hz}$ ;

- Measurements are obtained in batches of 2 at each time-step  $t$ , across 5 time-steps.
- True values of eigenfrequencies:  
 $\{f_1, f_2\} = \{3.271, 0.229\} \text{ Hz}$ .

# Application Problem B: 2DOF Shear Building

- The Bayesian model updating set-up to infer  $\boldsymbol{\theta} = \{k_1, k_2\}$  follows:
  - ❶  $P(k_1)$  is set as a Uniform prior with range:  $k_1 \in [1.0, 1.0 \times 10^5] \text{ N/m}$ ;
  - ❷  $P(k_2)$  is set as a Uniform prior with range:  $k_2 \in [1.0, 1.0 \times 10^5] \text{ N/m}$ ;
  - ❸  $P(\mathbf{D}|\boldsymbol{\theta})$  is set as a Bi-Normal distribution:

$$P(\mathbf{D}_t|\boldsymbol{\theta}) = \frac{1}{\sigma_1 \cdot \sigma_2 \cdot 2\pi} \cdot \exp \left[ \sum_{n=2t-1}^{2t} -\frac{(\tilde{f}_{1,n} - f_1(\boldsymbol{\theta}))^2}{2\sigma_1^2} - \frac{(\tilde{f}_{2,n} - f_2(\boldsymbol{\theta}))^2}{2\sigma_2^2} \right]$$

- $N_{samples} = 1000$  obtained from posterior via TMCMC;
- Results will be compared against MCMC (i.e. MH).

# Application Problem B: 2DOF Shear Building

# Application Problem B: 2DOF Shear Building

Note: SMC took 16.93 s (Ref: TMCMC took 22.00 s; MH took 0.27 s).
